Abstract

This report describes a general purpose computer package for analysis of the composite criterion model of Srinivasan and Shocker. (*Psychometrika*, Vol. 38, No. 4, p. 473). A standard format allows data for a wide range of applications to be analyzed using this package. The report describes the development of the package, including the data base and the FORTRAN codes for performing the analysis. The sample problem used by Srinivasan and Shocker is analyzed to demonstrate the package.

This model was proposed as a technique for analyzing a decision making of preferences when they are multiple conflicting criteria.

A COMPUTER PACKAGE FOR THE COMPOSITE CRITERION MODEL

The composite criterion model was proposed by Srinivasan and Shocker [4] as a technique for analyzing a decision maker's preferences when there are multiple conflicting criteria. The model is based on the assumed existence of a value function which assigns a cardinal score to any alternative. Associated with alternative i is a vector $[a_{ij}]$ of attribute values. The value function is assumed to be:

$$s_i = v([a_{ij}]) = \sum_j w_j a_{ij} \quad (1)$$

The goal of the composite criterion model is to use a limited number of explicit pairwise comparisons to reveal the proper values of the weights, w_j , for a given decision maker.

Given two alternatives, i and j , if the decision maker prefers i over j , then it is assumed that $s_i > s_j$, i.e.,

$$\sum_k w_k a_{ik} - \sum_k w_k a_{jk} \geq 0$$

$$\text{or } \sum_k (a_{ij} - a_{jk}) w_k \geq 0 \quad (2)$$

Thus, if we have a set, Ω , of pairwise comparisons, there is a corresponding set of constraints, (2), which must be satisfied by the weights w_k .

Since it is possible that the decision maker may err in the preference responses (or that the linear value function assumption is not completely satisfied), the feasible set defined by (2) for $(i, j) \in \Omega$ may be empty. In that case, we would like to determine a "best" set of weights.

The composite criterion model, as proposed by Srinivasan and Shocker, determines the set of weights which minimizes the sum of the infeasibilities

in the constraints (2):

$$\text{minimize} \quad \sum_{(i,j) \in \Omega} z_{ij} \quad (3)$$

$$\text{s.t.} \quad \sum_{k \in P} a_{ijk} w_k + z_{ij} \geq 0 \quad (i,j) \in \Omega \quad (4)$$

$$\sum_{k \in P} \sum_{(i,j) \in \Omega} a_{ijk} w_k = 1 \quad (5)$$

$$z_{ij} \geq 0 \quad (i,j) \in \Omega \quad (6)$$

$$w_k \geq 0 \quad k \in P_1 \quad (7)$$

$$w_k \leq 0 \quad k \in P_2 \quad (8)$$

$$w_k \text{ urs } k \in P_3 \quad (9)$$

$$P = P_1 \cup P_2 \cup P_3; \quad P_i \cap P_j = \emptyset \quad i \neq j$$

Note that in order to determine the weights, w_k , the linear programming problem (3) - (9) must be solved.

Any composite criterion problem is defined by the sets Ω , P_1 , P_2 , P_3 and the vectors $[a_{ijk}]$. Thus, it is reasonable to develop a general purpose data base and solution procedure. The package we have developed is based on the overall design illustrated in Figure 1. The LP optimizer is the XMP suite of FORTRAN routines developed by Marsten [1]. The entire package is written in FORTRAN (ANSI 66), is reasonably portable, and can accomodate problems with as many as 30 restricted attributes (or 15 unrestricted attributes) and 100 pairwise comparisons.

Parameter sizes on the CCMODL program can be increased to accommodate

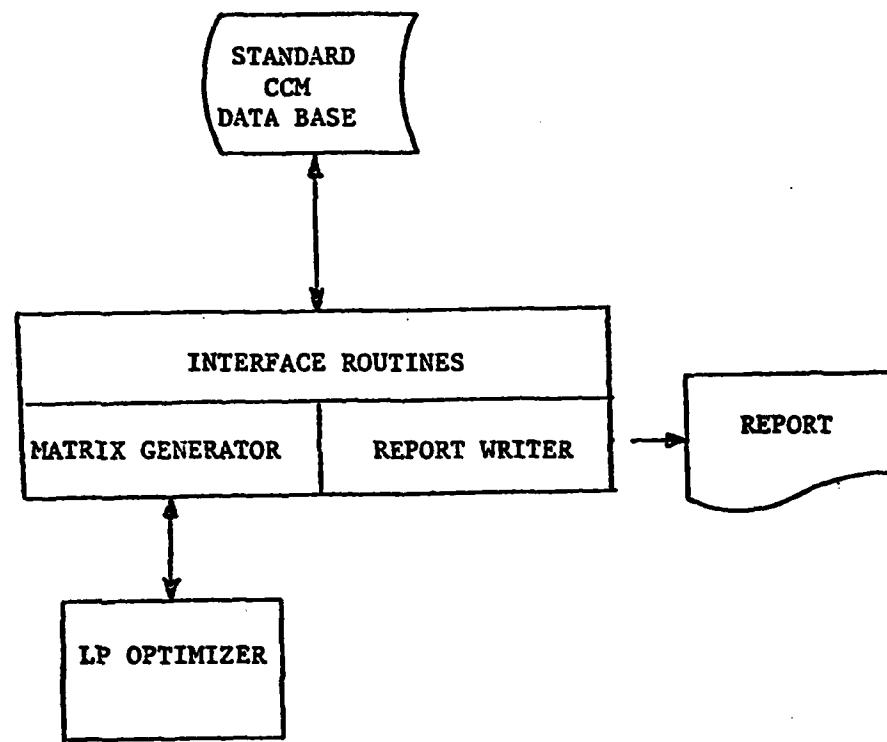

Figure 1. Overall System Design

any size problem with the amount of array space increasing as a function of the model parameters. Let:

MAXFPC = maximum number of forced-paired comparisons,
MAXWTS = maximum number of weights that can be specified where every unrestricted weight counts as two weights,
A = number of words required for array storage,

Then:

$$A \geq 63 \text{ MAXFPC} + 7 \text{ MAXWTS} + 4 (\text{MAXFPC}) (\text{MAXWTS}) \\ + \frac{12 (\text{MAXFPC} + 1) (\text{MAXWTS}) (\text{MAXFPC})}{\text{MAXWTS} + 3 \text{ MAXFPC} + 1} + 151$$

STANDARD CCM DATA BASE

The data base contains a complete description of the problem, from which the interface routines generate the LP coefficients. There are five record groups in the data base:

group 1: this is a title record to allow a description to appear on the report; (10A8) format,

group 2: this gives the magnitude of the problem;
(KATTA, KSTMLI, KFCOMP), where,
KATTA = number of attributes
KSTMLI = number of stimuli or alternatives
KFCOMP = number of paired comparisons
(3I5) format

group 3: a set of flags to indicate sign restrictions on the weights; the first record is

$$\text{KWFLAG} = \begin{cases} 1 & \text{if } P = P_1 \\ -1 & \text{if } P = P_2 \\ 2 & \text{if } P = P_3 \\ 0 & \text{otherwise} \end{cases}$$

(I2) format;

If KWFLAG = 0, then KATTA flags KW(i) are required, one for each attribute

$$\text{KW}(i) = \begin{cases} 1 & \text{if } i \in P_1 \\ -1 & \text{if } i \in P_2 \\ 2 & \text{if } i \in P_3 \end{cases}$$

(I2) format.

group 4: the set Ω ; KFCOMP pairs (i, j) are required where i is preferred to j
(2I4) format

group 5: attribute values; for each stimulus, a set of KATTA values are required, in (8F10.0) format; KSTMLI sets are required.

Example. Srinivasan and Shocker describe a small problem with five stimuli and three attributes. The data for this problem is given below:

$$\Omega = \{(1,2), (3,1), (1,4), (1,5), (2,3), (2,4), (5,2), (3,4), (3,5), (5,4)\}$$

$$* P = P_3$$

<u>Stimulus</u>	<u>Attribute Vector</u>
1	(2,6,6)
2	(3,4,7)
3	(5,4,4)
4	(6,3,2)
5	(8,1,3)

The standard CCM data set for this problem is given in Table 1.

* There is a small difference between this problem and the Srinivasan and Shocker problem in [4], the difference being that in [4] all weights are restricted to be non-negative while in this problem all weights are unrestricted.

LP OPTIMIZER

The LP optimizer is the XMP package developed by Marsten [1]. XMP implements a revised simplex algorithm and uses the LA05 subroutines to manage an LU factorization of the basis matrix from the Harwell library. XMP is written in a "Vanilla" FORTRAN where only very simple features of the language have been used. XMP operates in main memory where the memory space that XMP uses must be provided by the calling program. XMP is hierarchically structured and any XMP subroutine may be called at any level of the hierarchy.

The design objectives of XMP were flexibility, extensibility, and reliability with execution time as a secondary objective. XMP contains 46 subroutines, 10500 lines of FORTRAN and requires 10395 words for the object code.

INTERFACE ROUTINES

The interface code MCCMDL, consists of 551 lines of FORTRAN and is internally documented. The code requires 1246 words for the object code and 29708 words for arrays (this includes the arrays required for XMP). As presently configured, MCCMDL can accommodate 100 stimuli, 30 attributes and 100 paired comparisons. The number of paired comparisons is the critical parameter, since it increases both the number of variables and the number of constraints in the LP problem.

The CCMODL program was used to solve the problem described in the data set listed in Table 1, the output is shown in Table 2. The results shown in Table 2 are the same results obtained by Srinivasan and Shocker in [4]. The run was completed in .486 CP seconds.

As discussed in [4] and as seen in Table 2, stimuli 1, 2, 5 have the same score. This occurred because of the number of intransitivities in the pairwise comparisons in the example. Since every Z_i except $Z_5 = .02174$, is equal to zero this implies that every preferred stimulus in a pairwise comparison has a higher score than the other stimuli in the comparison except in comparison 5. In comparison 5 the Decision Maker preferred stimulus 2 to stimulus 3 when comparing scores we see that stimulus 3 has a higher score (by .02174) than does stimulus 2.

A listing of the FORTRAN source for MCCMDL is given in Appendix A.
